## Introduction

This document describes the MACsec feature, its use cases, and how to troubleshoot the feature on Catalyst 9000 switches. Scope of this document is MACsec on LAN, between two switches/routers.

## Prerequisites

### Requirements

There are no specific requirements for this document.

## Components Used

- C9300
- C9400
- C9500
- C9600

The information in this document was created from the devices in a specific lab environment. All of the

devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

---

**Note:** Consult the appropriate configuration guide for the commands that are used in order to enable these features on other Cisco platforms.

---

## Background Information

Clear text data communication is susceptible to security threats. Security breaches can occur at any layer of the OSI model. Some of the common breaches at Layer 2 are sniffing, packet eavesdropping, tampering, injection, MAC address spoofing, ARP spoofing, Denial of Service (DoS) attacks against a DHCP server, and VLAN hopping.

MacSec is an L2 encryption technology described in IEEE 802.1AE standard. MACsec secures the data on physical media, and makes it impossible for data to be compromised at higher layers. As a result, MACsec encryption takes priority over any other encryption method for higher layers, such as IPsec and SSL.

### Advantages of MacSec

**Client-Oriented Mode:** MACsec is used in setups where two switches that are peering with each other can alternate as a key server or a key client prior to exchanging keys. The key server generates and maintains the CAK between the two peers.

**Data Integrity Check:** MACsec uses MKA to generate an Integrity Check Value (ICV) for the frame that arrives on the port. If the generated ICV is the same as the ICV in the frame, then the frame is accepted; otherwise it is dropped.

**Data Encryption:** MACsec provides port-level encryption on the interfaces of switches. This means that the frames sent out of the configured port are encrypted and frames received on the port are decrypted. MACsec also provides a mechanism where you can configure whether only encrypted frames or all frames (encrypted and plain) are accepted on the interface.

**Replay Protection:** When frames are transmitted through the network, there is a possibility that frames get out of the ordered sequence. MACsec provides a configurable window that accepts a specified number of out-of-sequence frames.

### MACsec and MTU

The MACsec header adds up to 32 bytes of header overhead. Consider a larger system/interface MTU on switches in the path to account for the additional overhead added by the MACsec header. If MTU is too low, you might see unexpected packet loss/delay for applications that need to use higher MTU.

---

**Note:** If there is an issue related to MACSEC, please ensure the GBIC at both ends are supported per the [Compatibility Matrix](#).

---

## Where MACsec is Used

### Campus Use Cases

- Host-to-switch

- Between Sites or Buildings
- Between Floors in a Multi-tenancy

## Data Center Use Cases

- Data Center Interconnect
- Server-to-switch

## WAN Use Cases

- Data Center Interconnect
- Campus interconnect
- Hub-Spoke

## Terminology

<b>MKA</b>	MACsec Key Agreement	defined in IEEE 802.1X REV-2010 as a key agreement protocol for discovering MACsec peers and negotiating keys
<b>CAK</b>	Connectivity Association Key	long-lived master key used to generate all other keys used for MACsec. LAN implementations derive this from MSK (generated during EAP exchange)
<b>PMK</b>	Pairwise Master Key	One of the components used to derive the session keys that are used to encrypt traffic. Manually configured, or derived from 802.1X
<b>CKN</b>	CAK key name	used to configure the key value or CAK. Only even number of <u>HEX</u> characters up to 64 characters allowed.
<b>SAK</b>	Secure Association Key	derived by the elected Key Server from the CAK and is the key used by the router/end devices to encrypt traffic for a given session.
<b>ICV</b>	Integrity Check Value key	derived from CAK and is tagged in every data/control frame to prove the frame is from an authorized peer. 8-16 bytes depending cipher suite
<b>KEK</b>	Key Encrypting Key	derived from CAK (the preshared key) and used to protect the MacSec Keys
<b>SCI</b>	Secure Channel Identifier	Each virtual port receives a unique secure channel identifier (SCI) based on the MAC address of the physical interface concatenated with a 16-bit port ID

## Scenario 1: MACsec Switch to Switch link security with SAP in Pre-Shared Key (PSK) mode

### Topology

**Step 1.** Validate the configuration on both sides of the link

```
<#root>

9300_stack#
show run interface gig 1/0/1

interface GigabitEthernet1/0/1
description MACSEC_manual_3850-2-gi1/0/1
switchport access vlan 10
switchport mode trunk

cts manual

no propagate sgt

sap pmk
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA

mode-list gcm-encrypt <-- use full packet encrypt mode

3850#
show run interface gig1/0/1

interface GigabitEthernet1/0/1
description 9300-1gi1/0/1 MACSEC manual
switchport access vlan 10
switchport mode trunk

cts manual

no propagate sgt

sap pmk
AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA

mode-list gcm-encrypt

NOTE:

cts manual

<-- Supplies local configuration for Cisco TrustSec parameters
```

```
no propagate sgt
```

```
<-- disable SGT tagging on a manually-configured TrustSec-capable interface,
```

```
if you do not need to propagate the SGT tags.
```

```
sap pmk AAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAAA mode-list gcm-encrypt
```

```
<--
```

Use the sap command to manually specify the Pairwise Master Key (PMK) and the Security Association Proto-

authentication and encryption modes to negotiate MACsec link encryption between two interfaces.

The default encryption is sap modelist gcm-encrypt null

```
9300_stack#(config-if-cts-manual)#
```

```
sap pmk fa mode-list
```

```
?
```

```
gcm-encrypt GCM authentication, GCM encryption  
gmac GCM authentication, no encryption  
no-encap No encapsulation  
null Encapsulation present, no authentication, no encryption
```

Use "gcm-encrypt" for full GCM-AES-128 encryption.

These protection levels are supported when you configure SAP pairwise master key (sap pmk):

SAP is not configuredâ€“ no protection.

sap mode-list gcm-encrypt gmac no-encapâ€“ protection desirable but not mandatory.

sap mode-list gcm-encrypt gmacâ€“ confidentiality preferred and integrity required.

The protection is selected by the supplicant according to supplicant preference.

sap mode-list gmac â€“ integrity only.

sap mode-list gcm-encrypt-confidentiality required.

sap mode-list gmac gcm-encrypt-integrity required and preferred, confidentiality optional.

**Step 2.** Verify MACsec state, and the parameters/counters are correct

```
<#root>
```

```
### Ping issued between endpoints to demonstrate counters ###
```

```
Host-1#
ping 10.10.10.12 <-- sourced from Host-1 IP 10.10.10.11

## Scenario 2: MACsec Switch-to-Switch Link Security with MKA in Pre-Shared Key (PSK) mode

### Topology

### Step 1. Validate the configuration on both sides of the link

```

<#root>
C9500#
sh run | sec key chain

key chain KEY macsec
key 01
cryptographic-algorithm aes-256-cmac
key-string 7 101C0B1A0343475954532E2E767B3233214105150555030A0004500B514B175F5B05515153005E0E5E505C525

lifetime local 00:00:00 Aug 21 2019 infinite <-- use NTP to sync the time for key chains

mka policy MKA

key-server priority 200
macsec-cipher-suite gcm-aes-256
confidentiality-offset 0

```

```
C9500#  
sh run interface fo1/0/1  
  
interface fo1/0/1  
macsec network-link  
  
mka policy MKA  
  
mka pre-shared-key key-chain KEY
```

```
C9300#  
sh run interface te1/1/3  
  
interface te1/1/3  
macsec network-link  
  
mka policy MKA  
  
mka pre-shared-key key-chain KEY
```

**Step 2.** Validate MACsec is enabled and all parameters/counters are correct

```
<#root>  
### This example shows the output from one side, verify on both ends of MACSEC tunnel ###
```

```
C9500#

MKPDU Rx Validation..... 0  
MKPDU Rx Bad Peer MN..... 0  
MKPDU Rx Non-recent Peerlist MN.. 0

## **Step-3 to Step- 5**

Follow the same instructions mentioned in Scenario 1

---

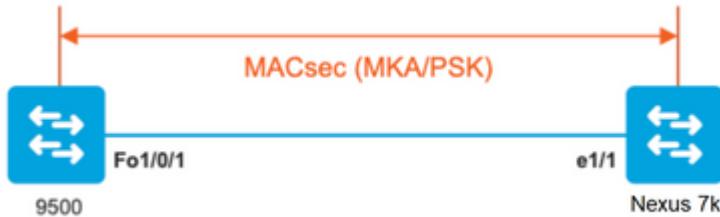

**Warning:** For interoperability purposes. Please be aware that some platforms do padding and some

platforms do not do, so this can lead to key issues where the mka session remains in "Init" state. You can verify this with "**show mka sessions**"

## Padding Issue Example

This use case shows a Catalyst 9500 and a Nexus 7k in NX-OS 8.2(2) but can also happen with Catalyst devices like C3560CX.

(Cisco bug ID [CSCvs92023](#) documents the problem).

- If you follow the configuration presented in Scenario 2, MKA won't establish the tunnel due to a key mismatch.
  - You must manually complete the key with 0's on the 9500 side since this device does not do padding.

Catalyst 9500

<#root>

**Nexus 7k**

<#root>

```
conf t
  key chain macsec1 macsec

key 01 --> Device does automatic padding.

  key-octet-string 12345678901234567890123456789012
  end
```

## Other Configuration Options

## MACsec Switch-to-Switch Link Security with MKA on Bundled/Port-Channel interface

- L3 and L2 Port-channels (LACP, PAgP and Mode ON)
- Encryption Types (AES-128 and AES-256 (AES-256 is applicable for Advantage License))
- Key Exchange MKA PSK only

Supported Platforms:

- Catalyst 9200 (AES-128 only)
- Catalyst 9300
- Catalyst 9400
- Catalyst 9500 and Catalyst 9500H
- Catalyst 9600

### Sample Switch to Switch Etherchannel Configuration

Key chain and MKA policy configuration remains same as shown earlier in MKA configuration section.

```
<#root>

interface <>  <-- This is the physical member link. MACsec encrypts on the individual links

macsec network-link

mka policy <policy-name>
mka pre-shared-key key-chain <key-chain name>
macsec replay-protection window-size frame number

channel-group <number> mode active  <-- Adding physical member to the port-channel
```

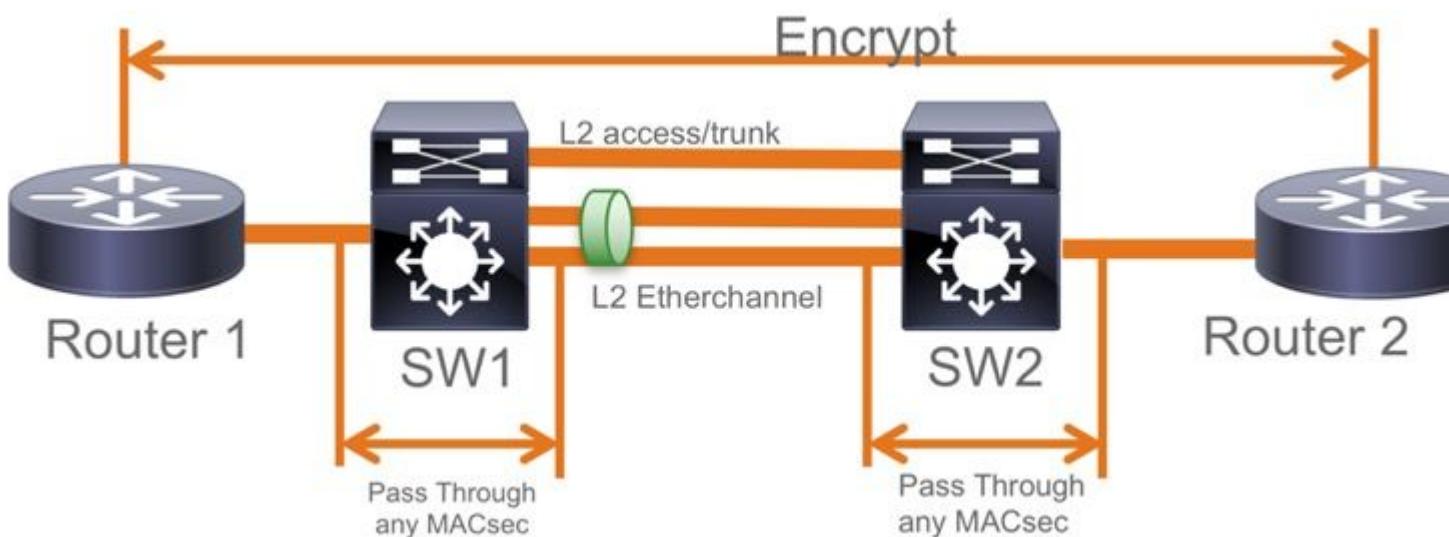

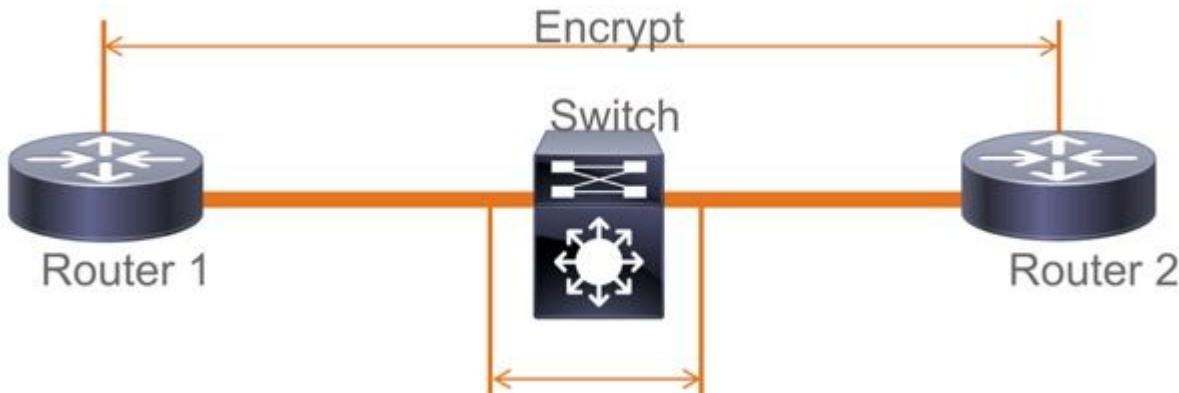

## MACsec Switch-to-Switch Link Security across L2 intermediate switches, PSK mode

This section covers some of those supported WAN MACsec scenarios where Cat9K needs to transparently pass encrypted packets.

There are cases when routers are not directly connected but they have L2 intermediate switches, and the L2 switches should bypass the encrypted packets without any processing of the encryption.

## Catalyst 9000 switches forward transparently packets with Clear Tag starting in 16.10(1)

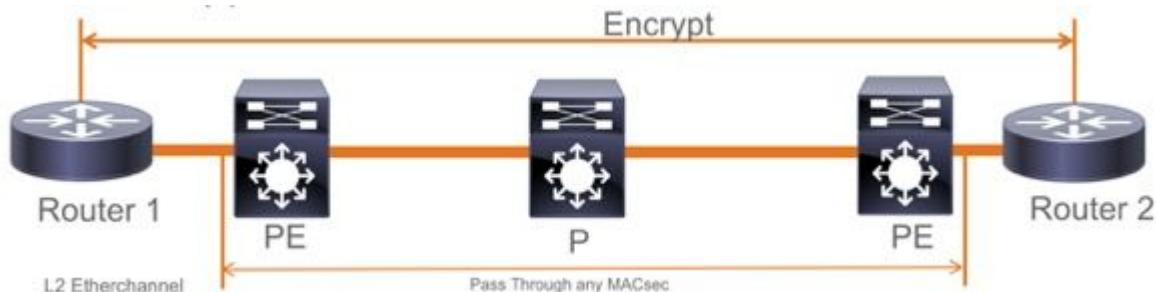

- Pass through is supported for MKA/SAP
- Supported on L2 access, trunk or Etherchannels
- Supported by default (no config CLIs to enable/disable)
- **Ensure routers send EAPOL frames with non-default (0x888E) ether-type**

## EoMPLS / VPLS Topology

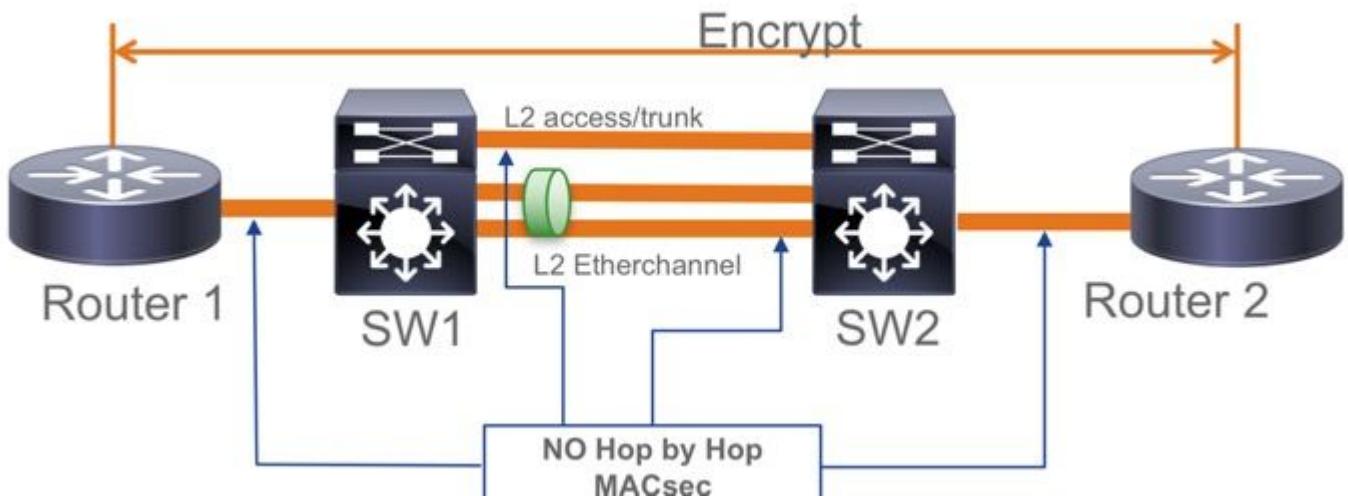

Supported Platforms Cat 9300/9400,9500/9500H as **PE** or **P** Devices

- VPLS
- EoMPLS
- Supported by default (no config CLIs to enable/disable)
- Start 16.10(1)

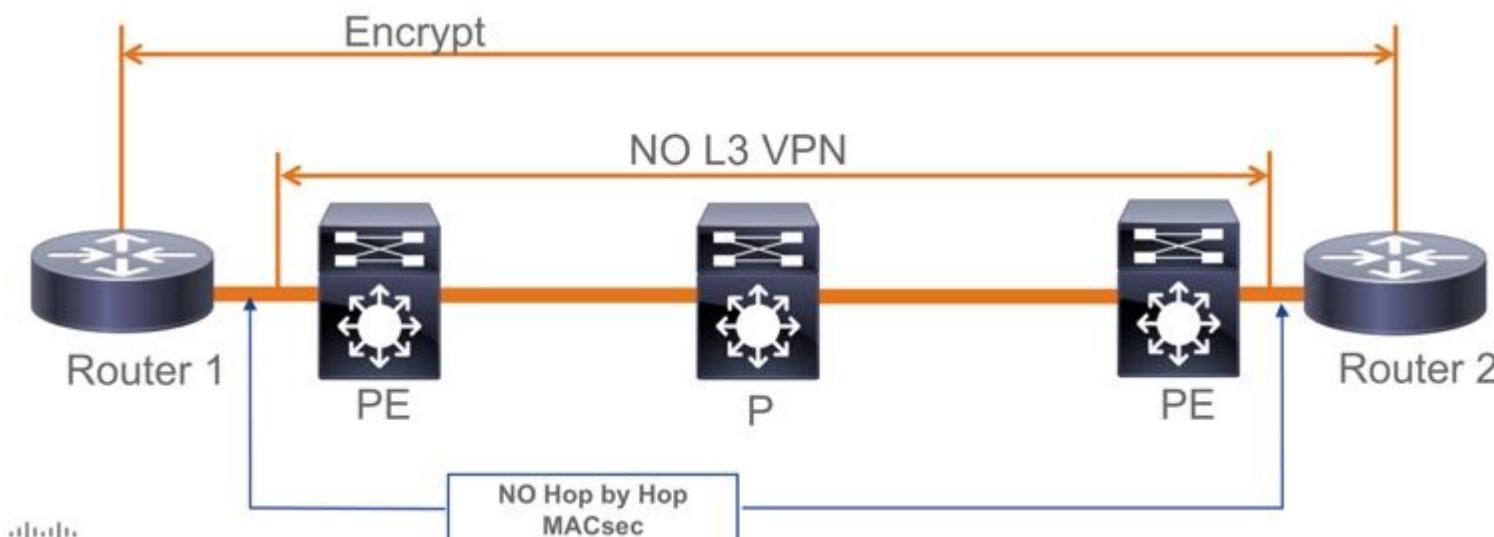

## Constraints

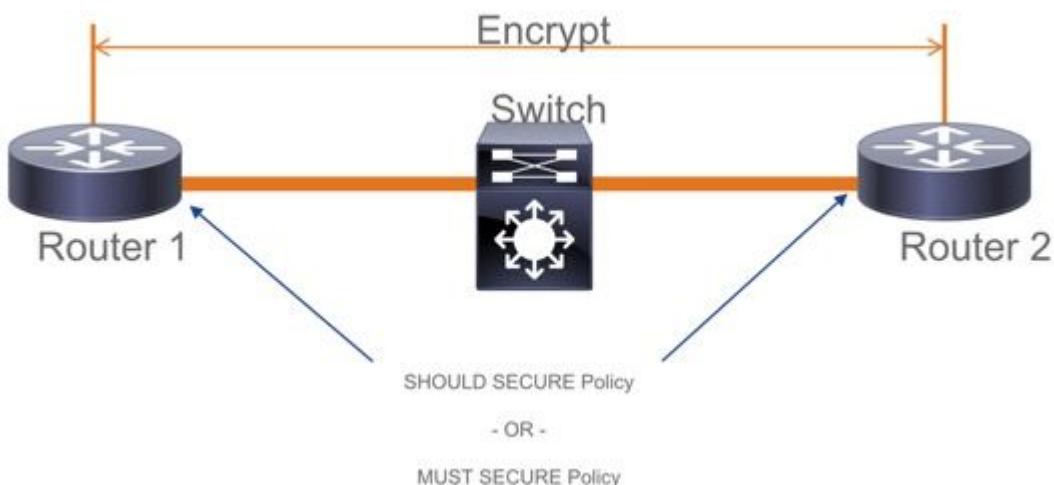

Double encryption is not supported. End to End MACsec with Clear tag require the Hop by Hop switches to not enable on the L2 directly connected Links

- ClearTag + EoMPLS with intermediate Layer 2 only switches, MACsec cannot enable on CE-PE link
- ClearTag + L3VPN with intermediate switches not supported

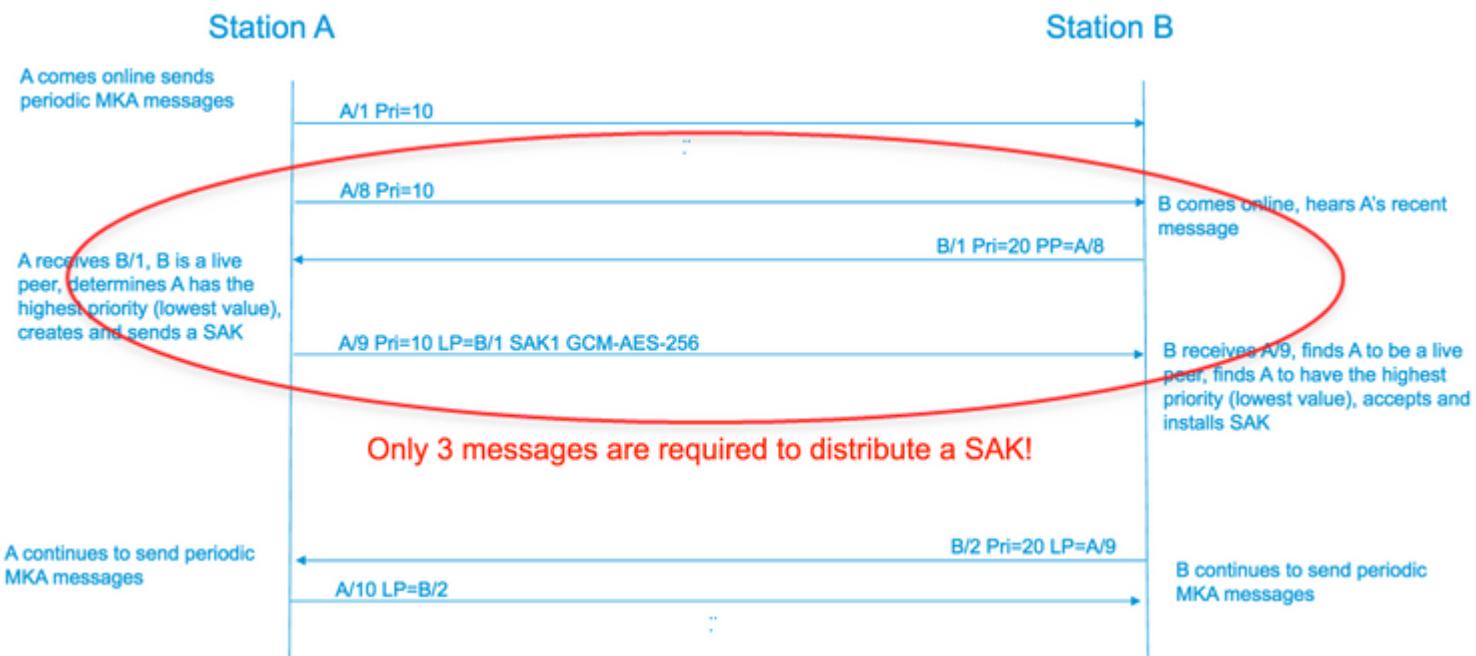

- There is no support for "Should Secure" in PSK Mode, "Must Secure" is the default mode
- Must Secure policy does not encrypt only EAPoL to negotiate the MACsec settings

# MACsec Operational Information

## Sequence of Operation

1. When the link and both end devices come up, they exchange MKA frames (**ether type = 0x888E**, same as EAPOL with packet type as MKA). Its a multi point to multipoint negotiation protocol. The CAK key value (normally static preshared), key name (CKN) must match and ICV must be valid for peers to be discovered and accepted.
2. The device with lowest Key Server priority (default = 0) is elected as the Key server. The Key server generates the SAK and distributes through MKA messages. Incase of tie highest value of SCI (secure Channel Identifier) wins.
3. Subsequently, all MacSec secured frames are encrypted with the SAK (Symmetric cryptography). There are separate TX and RX Secure Channels created. But same Key SAK is used for both encrypt and decrypt.
4. When a new device is detected in a multi access LAN (through EAPOL-MKA messages) the key server generates a new key to be used by all the devices. The new key comes into use after it is acknowledged by all devices (refer section 9.17.2 of IEEE Std 802.1X-2010).

## MACsec Packets

### Control frame (EAPOL-MKA)

- EAPOL destination MAC = 01:80:C2:00:00:03 to multicast the packets to multiple destinations
- EAPOL ether type = 0x888E

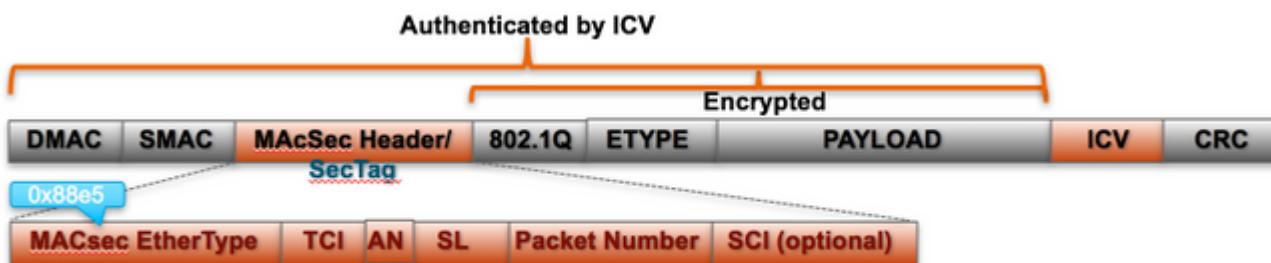

### L2 payload in the Control frame format

Protocol Version	
Packet Type = EAPOL-MKA	
Packet Body Length	Size
Packet Body (MKPDU)	Basic Parameter Set Multiple of 4 octets
	Parameter Set Multiple of 4 octets
	Parameter Set Multiple of 4 octets
	ICV 16 octets

## Data frame

MACSec inserts two additional tags on data frames with maximum overhead of **32bytes** (min 16 byte).

- **SecTag** = 8 to 16 bytes (8 byte SCI is optional)
- **ICV** = 8 to 16 bytes based on the cipher suit (AES128/256)

**MACsec Tag Format**

Field	Size	Description
Ethertype	16 bit	MAC length/type value for MACsec packet EtherType = 88-E5
TCI	6 bit	Tag control info contains: Version, ES, SC, SCB, E, C (indicates how frame is protected)
AN	2 bit	Association number
SL	8 bit	Short Length Indicates MSDU length of 1-48 octets 0 indicates MSDU length > 48 octets
PN	32 bit	Packet sequence number
SCI	64 bit	Secure channel identified (optional)

## SAP Negotiation

# SAP Negotiation

## Pair-wise Master Key (PMK)

(Manually configured or derived through 802.1X authentication)

PMK is never sent on the link

**Role determination:** Lowest MAC = Authenticator (Manual Mode), RADIUS server tells who is who (802.1X Mode)

Authenticator and Supplicant derive keys and exchange with each other

$$\text{PMKID(16)} = \text{HMAC-SHA1-128(PMK, "PMK Name" || AA || SA)}$$

AA: Authenticator Address, SA: Supplicant Address

$$\text{PTK} \leftarrow \text{PRF-X(PMK, "Pairwise key expansion", Min(AA,SA) || Max(AA,SA) || Min(ANonce, SNonce) || Max(ANonce, SNonce))}$$

ANonce & SNonce = Random values gen by Authenticator & Supplicant respectively

Pairwise Transient Key PTK

Key Confirmation Key (KCK)	Key Encryption Key (KEK)	Temporal Key (TK)
Message Integrity check (16)	Encryption Alg (16)	Data Encryption

## Key Exchange

# MACsec Key Derivation Schemes

## Session Key Agreement Protocols

SAP

**Security Association Protocol** is Cisco proprietary protocol for MACSec Key negotiation.

Used only for Switch-to-Switch encryptions.

MKA

**MKA (MACsec Key Agreement)** is defined in IEEE 802.1X-2010.

Used today for Switch-to-Host encryptions. Router MACsec uses MKA

CISCO

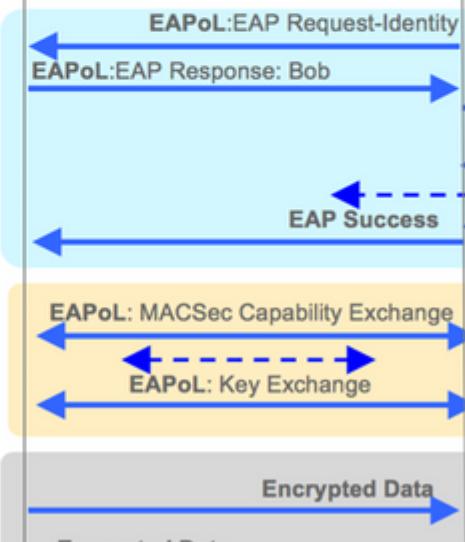

Software Supplicant

Authenti

1 IEEE 802.1X and Key Distribution

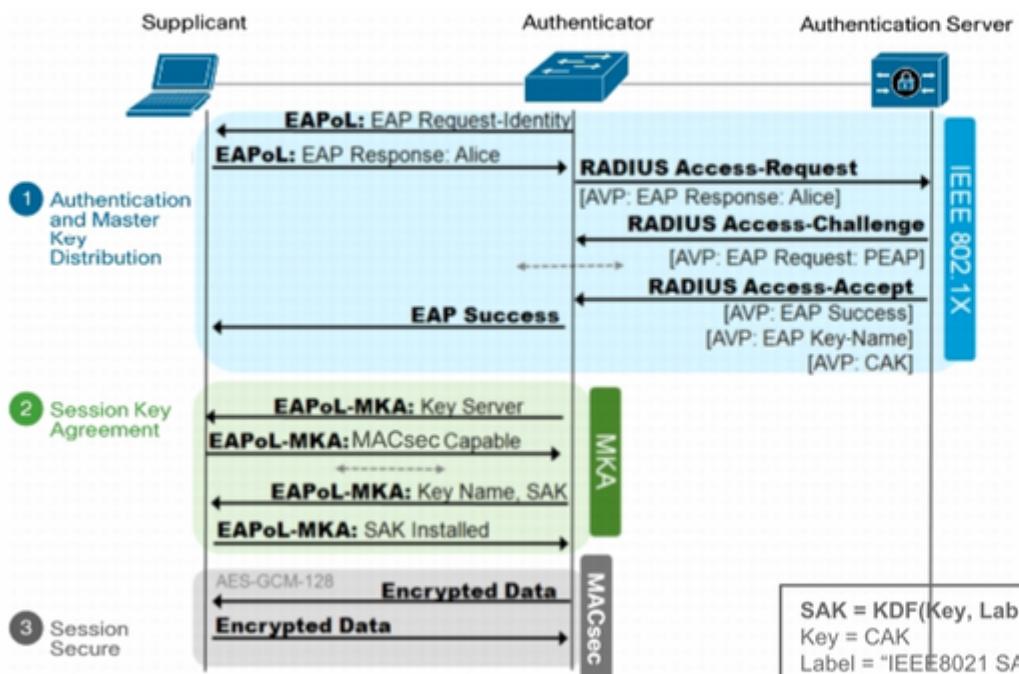

2 Session Key Agreement

3 Secure Session

# MKA Exchange

$$\text{ICV} = \text{AES-CMAC}(\text{ICK}, \text{M}, 128)$$

$$\text{M} = \text{DA} + \text{SA} + (\text{MSDU} - \text{ICV})$$

A pairwise CAK (Connectivity Association Key) is derived from the CAK.  
**CAK** = KDF(Key, Label, mac1 | mac2 | CAKlength)

**Key** = MSK[0-15] for a 128 bit CAK, MSK[0-31] for a 256 bit CAK  
**Label** = "IEEE8021 EAP CAK"  
**mac1** = the lesser of the two source MAC addresses  
**mac2** = the greater of the two source MAC addresses  
**CAKlength** = two octets representing an integer value (128 for a 128 bit CAK with the most significant octet first)

The KEK (Key Encryption Key) is derived from the CAK.  
**KEK** = KDF(Key, Label, Keyid, KEKLength)

**Key** = CAK  
**Label** = "IEEE8021 KEK"  
**Keyid** = the first 16 octets of the CKN, with the most significant octet first  
**KEKLength** = two octets representing an integer value (256 for a 256 bit KEK with the most significant octet first)

The ICK (ICV Key) is derived from the CAK.

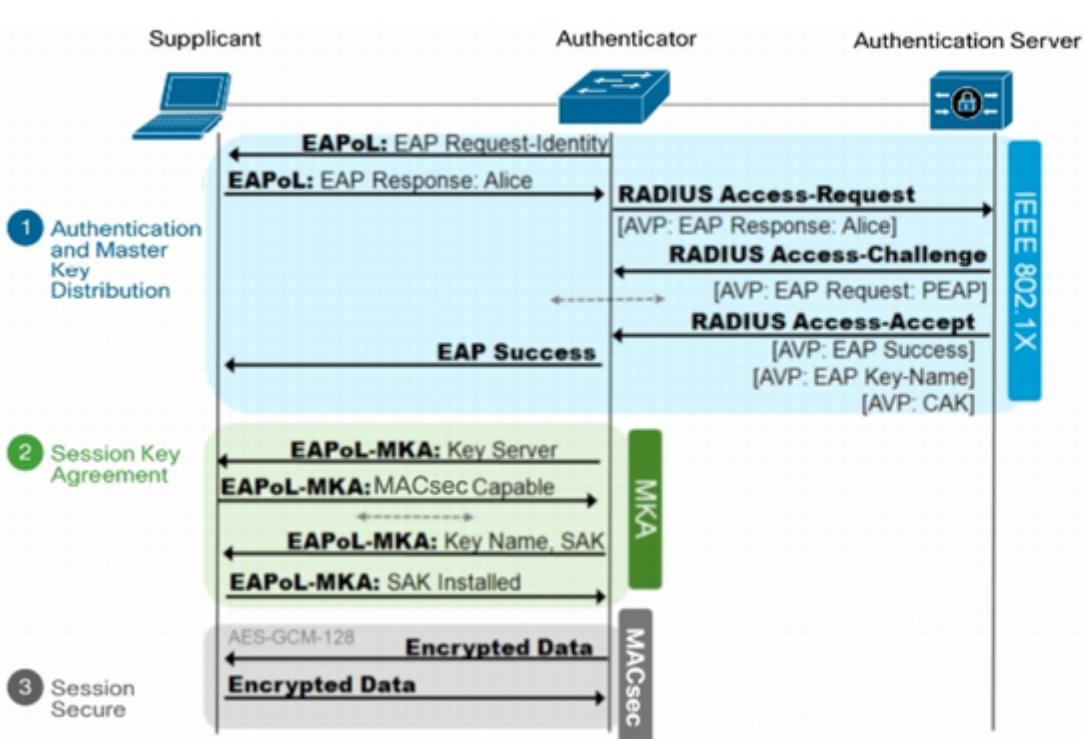

**ICK** = KDF(Key, Label, Keyid, ICKLength)

**Key** = CAK  
**Label** = "IEEE8021 ICK"  
**Keyid** = the first 16 octets of the CKN, with the most significant octet first  
**ICKLength** = two octets representing an integer value (256 for a 256 bit ICK with the most significant octet first)

**SAK** = KDF(Key, Label, KS-nonce | MI-value list | KN, SAKLength)

**Key** = CAK  
**Label** = "IEEE8021 SAK"  
**KS-nonce** = a nonce of the same size as the required SAK, obtained from the Key Server  
**MI-value list** = a concatenation of MI values (in no particular order)  
**KN** = four octets, the Key Number assigned by the Key Server as part of the SAK  
**SAKlength** = two octets representing an integer value (128 for a 128 bit SAK with the most significant octet first)
